

Cancer Bio Course 2025

Session 2: Introduction to cancer biology

Bridge and Engage Scholars

August 13th, 2025

Memorial Sloan Kettering
Cancer Center

Pablo Sánchez Vela, MD

Senior Research Scientist

Ross Levine Lab

Molecular Cancer Medicine Service

Human Oncology and Pathogenesis Program

sanchezp@mskcc.org

Course structure

In-person activities:

- Session 1 – Introduction to course and basic techniques applied in basic cancer research

- Session 2 – Paper discussion
- Session 3 – Paper discussion
- Session 4 – Paper discussion

+ Presentations!!

- Session 5 – Guided live research activity

- **Explanation of the question under research - why on earth did they decide to do this?**
- **Discussion figure by figure – is this paper not as good as authors think?:**
 - What is the point of each figure/panel?
 - Are there any missing experimental conditions?
 - Are results interpretable?
 - Do the results support the conclusions by the authors?
 - Would you have done anything differently?
 - Are there any missing experiments?
 - What are the limitations of the work?
 - What experiments could be done as a follow-up to the paper?

Experimental evidence in support of the dormant tumor cell

B FISHER, E R FISHER

PMID: 13823184 DOI: 10.1126/science.130.3380.918

Abstract

When rats were injected intraperitoneally with as few as 50 Walker-256 carcinosarcoma cells aarcoma cells and then examined 5 months later for hepatic tumor growth, none was evident. If, however, 3 months after injection the rats were subjected to repeated laparotomy and liver examination at 7-day intervals, 100 percent had a tumor within a few weeks.

RADICAL VERSUS TOTAL MASTECTOMY

TWENTY-FIVE-YEAR FOLLOW-UP OF A RANDOMIZED TRIAL COMPARING RADICAL MASTECTOMY, TOTAL MASTECTOMY, AND TOTAL MASTECTOMY FOLLOWED BY IRRADIATION

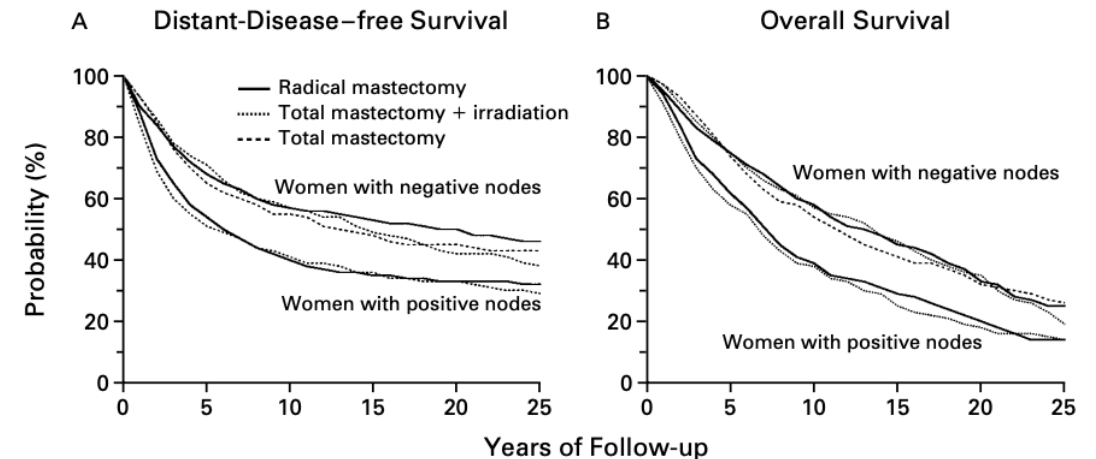

FIG. 2. Technique for superradical ma

Extended radical mastectomy

In one out of four cases of operable breast cancer internal mammary metastases are present. The internal mammary involvement of tumors of the outer quadrants is also considerable (18%), being especially frequent in cases with axillary metastases (41%). The 5- and 10-year survival rates show that the prognosis of cases with involvement of both axillary and internal mammary nodes is very poor; whereas, cases with internal mammary metastases only have an unexpectedly good prognosis. The removal of the internal mammary chain is essential for better prognostic evaluation and also seems justified by the radicality additionally given to the Halstead operation. However, only the results of a coordinated clinical trial will give a reliable evaluation of the true value of the procedure. A new technique of super-radical operation is described. The operation is safe, without considerable functional or cosmetic impairment. However, only long-term results will allow evaluation of its effectiveness.

Second generation cancer treatments: Radiation therapy

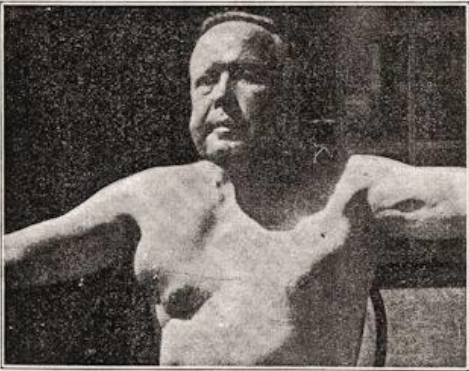

Fig. 1 (case 2).—Appearance in terminal lymphosarcoma in the radiation resistant stage four days after initiation of tris(beta-chloroethyl)amine hydrochloride therapy. Improvement in well-being, strength, appetite and temperature but no visible change in size of tumor masses.

Fig. 2 (case 2).—Eight days later and two days after the last dose. Complete disappearance of tumor masses in axillas, neck, jaw and thorax, with decided improvement in the patient's condition.

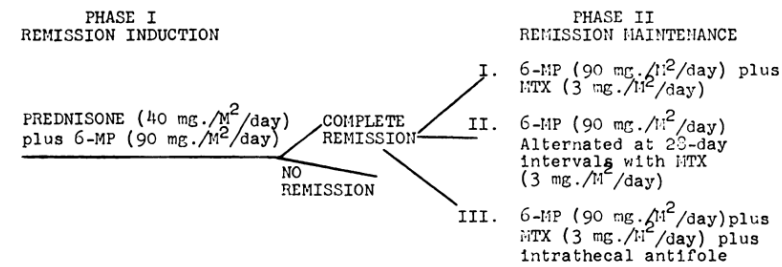

The occurrence of what he interpreted as an "acceleration phenomenon" in the leukemic process as seen in the marrow and viscera of children with acute leukemia treated by the injection of folic acid conjugates¹ — pteroyltriglutamic acid (teropterin) and pteroyldiglutamic acid (diopterin) — and an experience gained from studies on folic acid deficiency suggested to Farber that folic acid antagonists might be of value in the treatment of patients with acute leukemia.² Post-mortem studies of leukemic infiltrates of the bone marrow and viscera in patients treated with folic acid conjugates were regarded by Farber as evidences of an acceleration of the leukemic processes to a degree not encountered in his experience with some 200 post-mortem examinations on children with acute leukemia not so treated. It appeared worth while, therefore, to ascertain if this acceleration phenomenon could be employed to advantage either by radiation or nitrogen mustard therapy after pretreatment with folic acid conjugates or by the administration of antagonists to folic acid.² A series of folic acid antagonists was made available by Dr. Y. Subbarow and his colleagues.³⁻⁵ Farber et al. NEJM 1948

SCREENING DATA FROM THE CANCER CHEMOTHERAPY NATIONAL SERVICE CENTER SCREENING LABORATORIES. XLIII.

Saul A. Schepartz,¹ Betty J. Abbott,² and Joseph Leiter³

SUMMARY

Data are reported on 1592 synthetic compounds which were tested in the CCNSC primary screens. Almost all of the compounds were tested in Sarcoma 180, Adenocarcinoma 755, Leukemia 1210, and KB cells in culture; some tests were also carried out in Friend virus leukemia, Ehrlich ascites, Human epidermoid carcinoma HEp2, Lewis lung carcinoma, and Walker 256 (intramuscular). Data are reported only on compounds which have not demonstrated sufficient activity in these systems to warrant further investigation. The number of test systems in the screening program has been reduced; the reasons for the reduction are discussed.

Regimen	No. of Patients	No. (%) of Treatment Failures	Median Survival
MOPP	123	62 (50)	4.84
ABVD	115	44 (38)	None
MOPP-ABVD	123	43 (35)	None
All	361	149 (41)	—

Yet, chemotherapy acceptance was hard

Bonadonna et al. 1976 NEJM

...developed by the NCI but was performed under contract with the Milan Cancer Institute, despite large populations of patients with operable breast cancer in the United States, because **no major U.S. center was willing to test combination chemotherapy as an adjuvant...**

The results of both studies were positive, and the race was on. By 1991, thanks to the **availability of multiple effective chemotherapeutic agents and hormone treatments, improved diagnostic tools for early diagnosis, and intelligently designed clinical trials, the rate of death from breast cancer began to fall**, a trend that has continued.

The image shows two magazine covers side-by-side. The left cover is for 'nature' magazine, featuring a colorful, abstract, and somewhat pixelated image of a landscape or biological structure. The title 'nature' is in a large, white, serif font at the top. Below it, the subtitle 'the human genome' is written in a smaller, white, sans-serif font. The right cover is for 'Science' magazine, featuring a black and white photograph of a man and a woman looking towards the camera. The title 'Science' is in a large, white, serif font at the top. Below it, the subtitle 'the human genome' is written in a smaller, white, sans-serif font. Both covers have a white border.

[illegible]

“Whether it was Cancer or Alzheimer’s or another condition [...] We clearly needed fundamental basic research to understand those diseases before we could hope to cure them.” — Benno Schmidt 1995

The graph displays two metrics over time for the 65+ age group. The x-axis represents the 'Year of Death' from 1975 to 2015. The left y-axis represents the 'Rate per 100,000' (500 to 3,000), and the right y-axis represents the 'Survival probability' (0.0 to 1.0). The blue line (Rate per 100,000) starts at approximately 2,750 in 1975 and declines to about 1,050 by 2015. The red line (Survival probability) starts at approximately 0.98 in 1975 and declines to about 0.85 by 2015.

Year of Death	Rate per 100,000 (Blue Line)	Survival probability (Red Line)
1975	2,750	0.98
1980	2,600	1.00
1985	2,400	1.02
1990	2,100	1.05
1995	1,900	1.05
2000	1,600	1.02
2005	1,400	1.00
2010	1,150	0.95
2015	1,050	0.85

Cancer therapy shapes the fitness landscape of clonal hematopoiesis

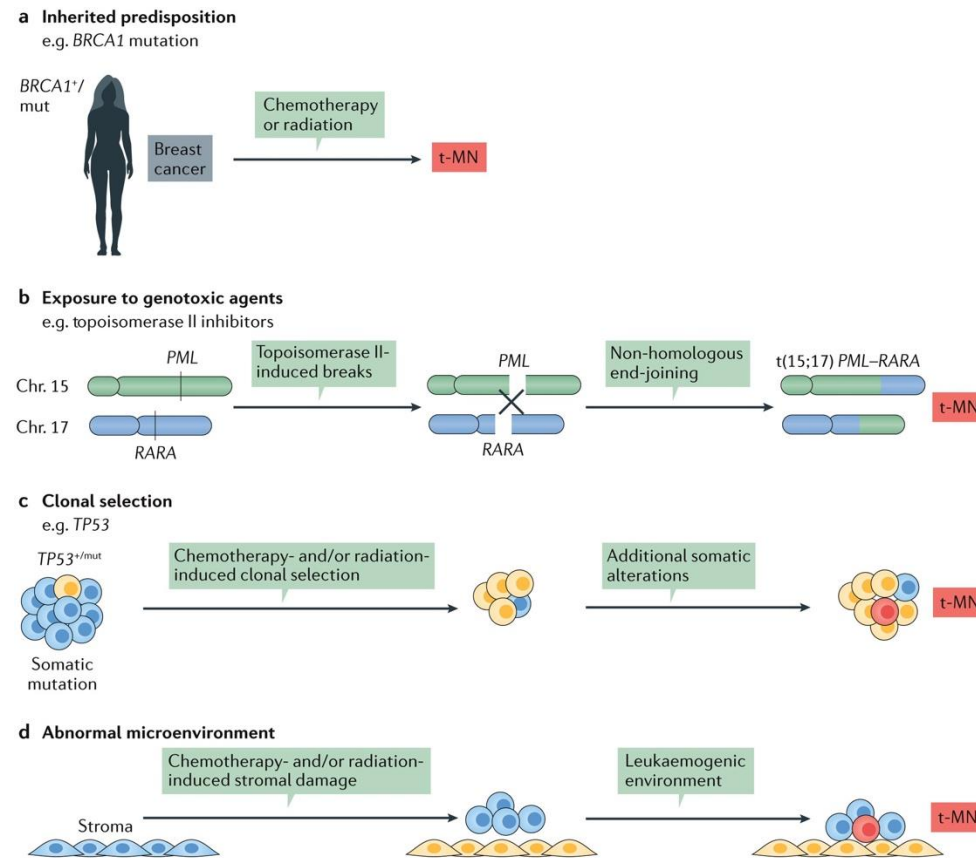

Kelly L. Bolton¹, Ryan N. Ptashkin^{2,34}, Teng Gao^{3,34}, Lior Braunstein⁴, Sean M. Devlin⁵, Daniel Kelly⁶,

Paper discussion

- **Explanation of the question under research** - *why did they decide to do this?*
- **Discussion figure by figure** – *is this paper not as good as authors think?:*
 - What is the point of each figure/panel?
 - Are there any missing experimental conditions?
 - Are results interpretable?
 - Do the results support the conclusions by the authors?
 - Would you have done anything differently?
 - Are there any missing experiments?
 - What are the limitations of the work?
 - What experiments could be done as a follow-up to the paper?

Both intrinsic and extrinsic factors contribute to the development of therapy-related myeloid neoplasms.

Nature Reviews | Cancer

Research Question

- **Explanation of the question under research - *why did they decide to do this?***

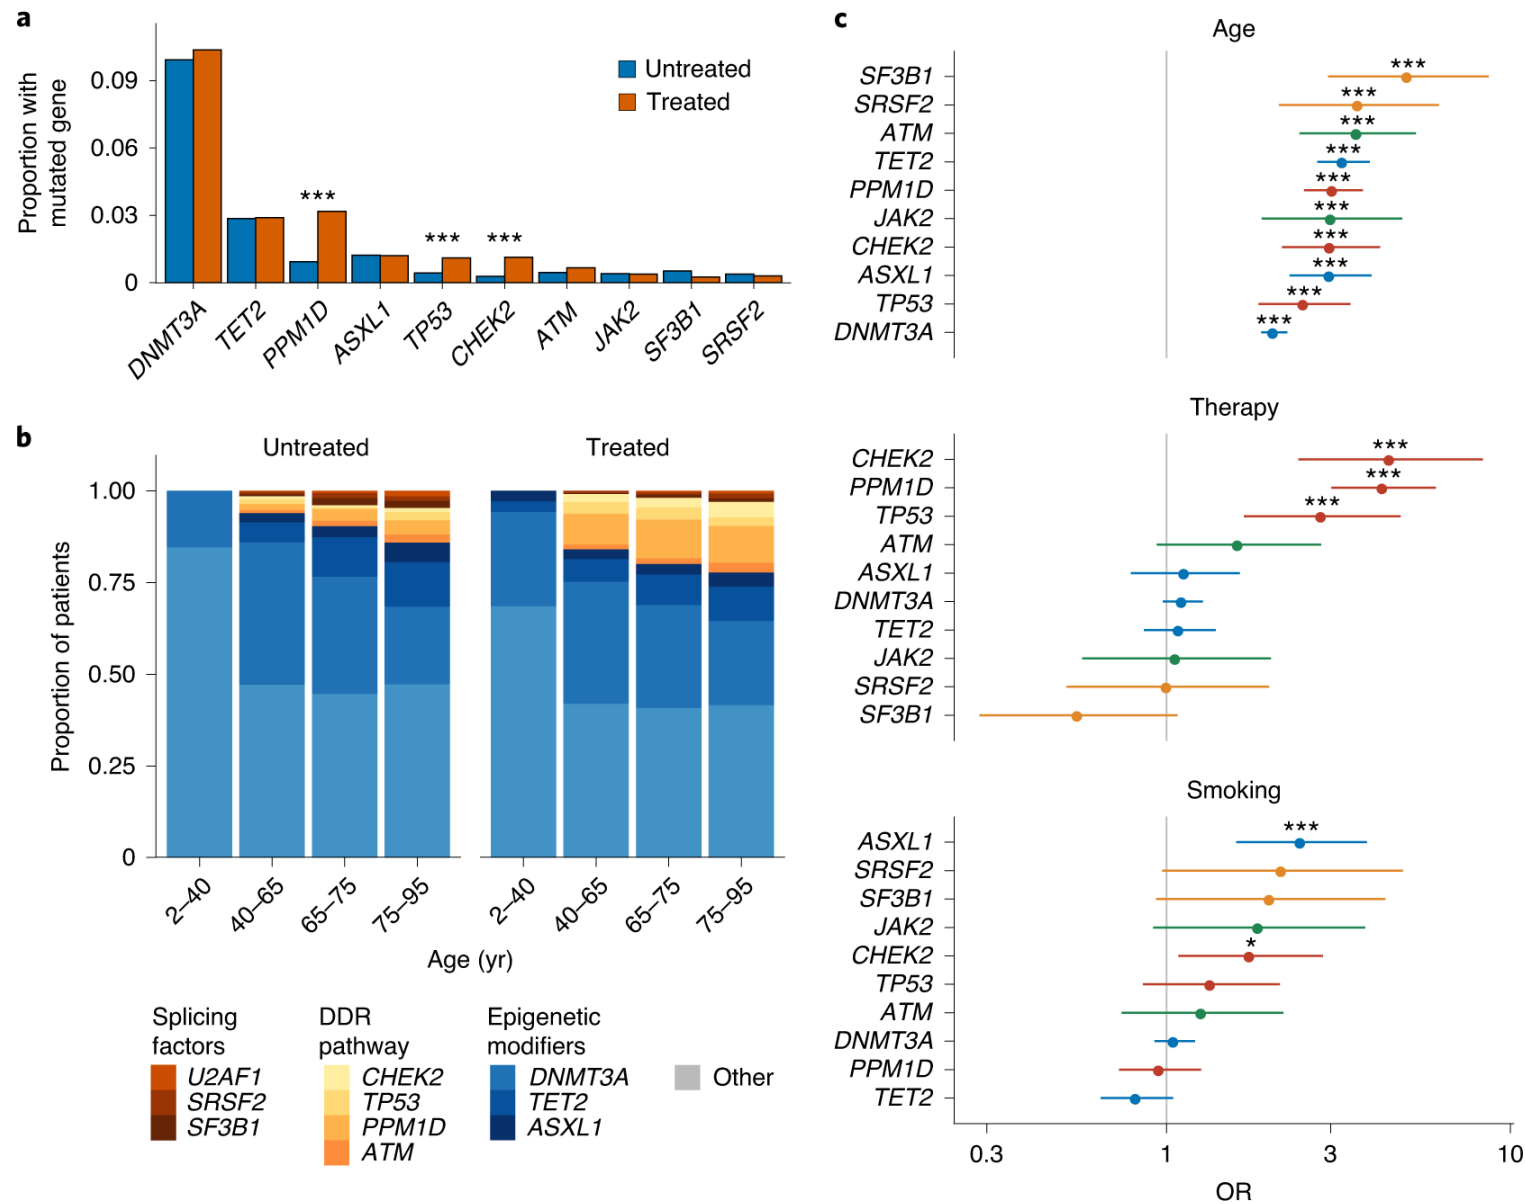

“understanding of the processes that drive transformation of certain clones to cancer is limited. Here we study this phenomenon in the context of clonal hematopoiesis (CH) and the development of therapy-related myeloid neoplasms (tMNs).”

What is the impact of the study?

“A detailed characterization of the genomic landscape of breast cancer metastasis could provide important insights including identifying:

- (1) genomic drivers of metastatic disease progression,
- (2) the extent and clinical impact of tumoral heterogeneity,
- (3) the biologic determinants of variable response of individual patients to different therapies, and
- (4) additional potential therapeutic targets.”

Figure 1
